(54) Title: RECEIVER WITH AGC CONTROLLED RESONANCE AMPLIFIER

(57) Abstract: Receiver comprising a resonance amplifier for selectively amplifying a modulated carrier signal being coupled to signal demodulation means for narrow band demodulation. Said resonance amplifier comprising a cascade of first and second transconductance amplifiers (TC1, TC2) being included in a loop, outputs thereof being coupled via first and second parallel RC filters (R1C1; R2C2) to inputs of the second and first transconductance amplifiers (TC1, TC2), respectively, said loop also includes means for signal inversion (INV). Inputs and outputs of third and fourth transconductance amplifiers (TC3, TC4) are coupled to outputs of said first and second transconductance amplifiers (TC1, TC2), respectively, to effectuate a negative resistance value across said first and second parallel RC filters (R1C1, R2C2), respectively, varying with the gain of said third and fourth transconductance amplifiers (TC3, TC4), fifth and sixth transconductance amplifiers (TC5, TC6) are coupled between inputs and outputs of said resonance amplifier. In order to reduce the overall noise figure of the receiver, said AGC signal generating means derive first and second control signals (Iq, Id) from said first DC signal (A), said control signals (Iq, Id) being supplied to

gain control inputs of said third to sixth transconductance amplifiers (TC3, TC4, TC5, TC6).

WO 02/071604 A2

## Receiver with AGC controlled resonance amplifier

The invention relates to a receiver comprising a resonance amplifier for selectively amplifying a modulated carrier signal being coupled to signal demodulation means for narrow band demodulation of said carrier signal providing an RF carrier level indicative, first DC signal being supplied to a first input of AGC signal generating means, said resonance amplifier having a cascade of first and second transconductance amplifiers being included in a loop, outputs thereof being coupled via first and second parallel RC filters to inputs of the second and first transconductance amplifiers, respectively, said loop also including means for signal inversion, inputs and outputs of third and fourth transconductance amplifiers being coupled to outputs of said first and second transconductance amplifiers, respectively, to effectuate a negative resistance value across said first and second parallel RC filters, respectively, varying with the gain of said third and fourth transconductance amplifiers, fifth and sixth transconductance amplifiers being coupled between inputs and outputs of said resonance amplifier. Such receiver is known e.g. from US patent number 5,220,686 being herein incorporated by reference.

The known receiver comprises an automatic gain control (AGC) to stabilize the output signal of the signal demodulation means against variations of the RF reception field strength. The AGC signal generating means therefore derives from an RF carrier level indicative DC signal reflecting said RF reception field strength, a single control signal for a cascade of resonance amplifiers. This single control signal, hereinafter being referred to as first control signal, is used to vary the gain of said third and fourth transconductance amplifiers of each resonance

amplifier in the cascade, such that at a decreasing RF reception field strength the resonance amplifiers increase in both gain and selectivity. This results not only in amplitude stabilization but also in an adaptive noise level stabilization.

However, in the partial compensation of the positive resistance of the first and second parallel RC filters by the negative resistance provided by the third and fourth transconductance amplifiers the noise generated by said positive resistance adds to the noise generated by said negative resistance. Dependent on the actual values of these resistances, an increase in gain in response to a decrease in RF reception field strength, causes the noise figure of the resonance amplifier to increase more than proportional, therewith deteriorating the overall noise figure of the receiver as a whole.

It is a first object of the invention to improve the noise figure of a receiver as referred to hereabove.

It is a second object of the invention to increase the dynamic range and the dynamic selectivity of such known receiver.

It is a third object of the invention to secure control stability.

It is a fourth object of the invention to simplify the receiver concept providing optimization in terms of low noise figure and maximum dynamic range.

Now therefore, according to one of its aspects the invention is characterized by said AGC signal generating means deriving first and second control signals from said first DC signal, said first control signal being supplied to gain control inputs of said third and fourth transconductance amplifiers and said second control signal being supplied to gain control inputs of said fifth and sixth transconductance amplifiers, the first and second

control signals increasing at an increase of the first DC signal and vice versa, the first control signal stronger than the second control signal.

By applying the measure according to the invention the  
5 overall gain increase in the resonance amplifier, occurring in response to a decrease in the RF reception field strength of a wanted RF signal, is shared between a substantially frequency indifferent or wideband gain increase provided by the fifth and sixth transconductance amplifiers and a  
10 selective gain increase provided by the third and fourth transconductance amplifiers. This gain sharing reduces the gain to be provided by the third and fourth transconductance amplifiers in order to obtain stabilization of the signal level at the output of the signal demodulation means and  
15 inherent thereto also said negative resistance. The noise contribution of these third and fourth transconductance amplifiers in the above partial compensation of the positive resistance of the first and second RC filters is therewith reduced, resulting in a substantial improvement of the  
20 overall noise figure of the receiver.

The AGC described so far is immune to RF signals adjacent in frequency to the wanted RF signal carrier. If the RF reception field strength of such adjacent RF signals is much greater than the RF reception field strength of the  
25 wanted RF signal, then the dynamic input range of the signal demodulator means may easily be exceeded resulting in a severe deterioration of the demodulation function of said signal demodulation means. In particular, weak RF signals causing the known AGC to increase the gain of the resonance  
30 amplifier(s) preceding the demodulation means, give rise to overexcitation of the demodulation means, if being accompanied by strong adjacent RF signals. The simultaneous increase in selectivity appears in practice to be

insufficient to effectively suppress strong adjacent transmitter signals and to avoid said overexcitation.

To extend the dynamic receiver input range, while maintaining the above improvement of the overall noise figure, a preferred embodiment of a receiver according to the invention is characterized by wideband level detecting means following the resonance amplifier supplying a wideband RF signal level indicative, second DC signal to a second input of said AGC signal generating means, said second control signal varying with a variation of the second DC signal.

With said second DC signal, this measure introduces a new AGC parameter allowing to reduce the dynamic variation of the wideband output signal of the resonance amplifier to values within the dynamic input range of the signal demodulation means, separately from the narrow band level stabilization obtained at the output of the signal demodulation means with the first DC signal. The signal demodulation means may therewith be prevented from being overexcited for field strength distributions of transmitter signals, which in practice normally occur.

A further preferred embodiment of a receiver according to the invention allowing to obtain an appropriate gain and selectivity setting of the resonance amplifier with simple circuitry, while preventing instabilities from occurring is characterized in that said second control signal varies opposite to the second DC signal.

An improvement in the wideband and narrowband level stabilization in terms of minimum noise figure and maximum dynamic range is obtained in a further preferred embodiment being characterized in that said first control signal varies substantially in correspondence with the first DC signal and the second control signal in proportion with the first DC signal and opposite to the second DC signal.

A practical embodiment of the latter further preferred embodiment, which takes into account the statistic distribution of weak and strong RF transmitter signals over the RF broadcast frequency range is characterized in that the proportion by which the second control signal varies with the first DC signal is in the order of magnitude of one quarter.

Another preferred embodiment of a receiver according to the invention using the above new AGC parameter to obtain an appropriate gain and selectivity setting of the resonance amplifier in terms of noise figure and dynamic selectivity, while preventing instabilities from occurring is characterized in that said second control signal decreases at a decrease of the second DC signal.

To optimize the gain and selectivity setting of the resonance amplifier, the latter embodiment is preferably characterized in that said first control signal varies substantially in correspondence with the first DC signal and opposite to the second DC signal and said second control signal substantially in correspondence with the product value of the first and second DC signals.

To set the respective stabilization levels at the output of the signal demodulation means and at the output of the resonance amplifier to appropriate values, another preferred embodiment of the invention is characterized by said signal demodulation means and said wideband level detecting means being coupled through first and second DC signal generating means to the first and second inputs of said AGC signal generating means in which the RF carrier level and the wideband RF signal level are being compared with first and second setlevel values, respectively.

For reason of stability the second set level is preferably chosen to be greater than the first setlevel.

Yet another preferred embodiment of a receiver according to the invention is characterized by a local tuning oscillator being controlled by a tuning voltage and providing a local RF oscillator signal to a synchronous RF demodulator included in said signal demodulation means, said tuning voltage being supplied to gain control inputs of said first and second transconductance amplifiers of said resonance amplifier.

This measure provides accurate parallel tuning of the passband characteristic of the resonance amplifier and the synchronous detection of the wanted RF signal by the synchronous RF demodulator.

Another preferred embodiment of the invention improving separation in AGC between the first and second DC signals is characterised by said tuneable resonance amplifier supplying a pair of phase quadrature RF signals to a square law envelope detector included in said wideband level detecting means.

By applying this measure, wideband RF signal detection is obtained by square law envelope detection of the RF signals at the output of the resonance amplifier(s) applying squaring of the phase quadrature RF I and Q signal components thereof, therewith increasing level differences between a weak wanted RF signal and its strong adjacent RF signals.

These and further aspects and advantages of the invention will be discussed more in detail hereinafter with reference to the disclosure of preferred embodiments, and in particular with reference to the appended Figures in which like reference numerals refer to like elements wherein:

Figure 1 is a schematic diagram of a prior art resonance amplifier;

Figure 2 is a block diagram of a preferred embodiment of a receiver according to the invention;

Figure 3a is a block diagram of a wideband an alternative embodiment of the AGC signal generating means CG as used in the receiver of Figure 2;

Figure 3b is a block diagram of a square law envelope  
5 detector for use as wideband level detecting means WD in a receiver according to the invention;

Figure 4 is a signal plot illustrating the functioning of the AGC system in the receiver of Figure 2.

Figure 1 shows a prior art tunable resonance amplifier  
10 RA comprising a cascade of first and second gain controlled transconductance amplifiers TC1 and TC2 being included in a non-regenerative DC negative feedback loop. An output of TC2 is therein negatively fed back through an inverter INV to an input of TC1 and outputs of TC1 and TC2 being coupled to  
15 respective mass connected parallel RC members R1C1 and R2C2, TC1 and R1C1 respectively TC2 and R2C2 functioning as first and second active poly-phase transconductance filter sections. The common connections of TC1 and R1C1, respectively TC2 and R2C2, constitute quadrature current inputs I<sub>in</sub>,  
20 respectively I'<sub>in</sub> and/or quadrature voltage outputs V<sub>out</sub>, respectively V'<sub>out</sub>. By supplying a tuning control current I<sub>t</sub> to control terminals of said first and second gain controlled transconductance amplifiers TC1 and TC2 the gain of TC1 and TC2 is varied and therewith the resonance frequency f<sub>res</sub> or  
25 center passband frequency of the tuneable resonance amplifier RA.

The tuneable resonance amplifier RA is also provided with third and fourth controllable transconductance amplifiers TC3 and TC4, each of which is fed back from the output to the  
30 input and is arranged at the outputs of TC1 and TC2, respectively. These transconductance amplifiers TC3 and TC4 provide negative resistances being arranged parallel to the parallel RC members R1C1 and R2C2, respectively. Fifth and sixth transconductance amplifiers TC5 and TC6 are included

between quadrature voltage inputs  $V_{in}$  and  $V'_{in}$  of the tuneable resonance amplifier RA on the one hand and the above current inputs  $I_{in}$  and  $I'_{in}$  of the tuneable resonance amplifier RA on the other hand.

5 In a phase quadrature mode of operation, the quadrature voltage inputs  $V_{in}$  and  $V'_{in}$  and/or the quadrature voltage outputs  $V_{out}$  and  $V'_{out}$  of the tuneable resonance amplifier RA are available for supplying thereto and/or taking therefrom a pair of phase quadrature signals. In a single phase mode of  
10 operation, the quadrature voltage inputs  $V_{in}$  and  $V'_{in}$ , respectively the quadrature voltage outputs  $V_{out}$  and  $V'_{out}$  are mutually coupled allowing to use the tuneable resonance amplifier RA to selectively amplify a single phase RF input signal into a single phase RF output signal.

15 The gain of the third and fourth controllable transconductance amplifiers TC3 and TC4 can be varied by means of a first control signal  $I_q$ . Such gain variation causes the above negative resistances being arranged parallel to the parallel RC members  $R1C1$  and  $R2C2$  to vary as well and along  
20 therewith the bandwidth or selectivity of the tuneable resonance amplifier RA as a whole. A variation in the second control current  $I_q$  therefore results in a variation of the selective gain of the resonance amplifier RA.

A frequency indifferent variation of the overall gain of  
25 the tuneable resonance amplifier RA without affecting its resonance frequency  $f_{res}$  and/or bandwidth is obtained by varying the gain of the transconductance amplifiers TC5 and TC6 by means of a control current  $I_d$ .

The description of the resonance amplifier RA given so  
30 far is sufficient for a proper understanding of the invention. For further details reference is made to US patent number 5,220,686.

Figure 2 shows a preferred embodiment of a receiver according to the invention, antenna means ANT being coupled

to an RF input circuit RFC comprising a cascade of resonance amplifiers RA1 to RAn for selectively amplifying a modulated RF carrier signal. The RF input circuit RFC is coupled to a synchronous demodulator SD functioning as signal

5 demodulation means, as well as to a phase detector PD being included in a phase locked loop (PLL). The phase detector PD is followed therein by a loop filter LP, an output thereof being coupled to a first control input of a voltage controlled oscillator VCO and providing a pair of phase  
10 quadrature local RF oscillator signals having RF in-phase and phase quadrature signal components I and Q. A tuning current  $I_t$  is supplied to a second control input of the voltage controlled oscillator VCO allowing to tune the oscillator frequency to the carrier frequency of a wanted RF  
15 signal. The voltage controlled oscillator VCO therewith also functions as tuning oscillator TO. The RF in-phase and phase quadrature signal components I and Q are being supplied to local carrier inputs of said phase detector PD and said synchronous demodulator SD, respectively. In an in-lock  
20 operation of the PLL, the RF in-phase signal component I of the pair of phase quadrature local RF oscillator signals is phase synchronized with the carrier frequency of the wanted RF signal and effectuates a synchronous demodulation of the wanted RF signal into its baseband modulation signal e.g. an  
25 audiosignal. A selection and processing of this baseband audiosignal takes place in an audio signal processing device ASP followed by sound reproduction in a loudspeaker system LS.

To obtain accurate parallel tuning of the passband  
30 characteristic of the resonance amplifier(s) of the RF input circuit RFC with the local oscillator frequency, the above tuning voltage  $V_t$  is supplied to the tuning oscillator TO and to gain control inputs of said first and second transconductance amplifiers as well.

The synchronous demodulator SD is also coupled through first DC signal generating means DC1 and AGC signal generating means CG to gain and bandwidth control inputs of the resonance amplifiers RA1-RAn of the RF input circuit RFC, therewith forming a first AGC loop, as will be described in more detail hereinafter.

In addition to the above baseband modulation signal the synchronous demodulator SD also provides a narrow band RF carrier level indicative DC signal, which is selected and further processed into a first DC loop signal in said first DC signal generating means DC1. In this further processing the RF carrier level indicative DC signal is being compared with a first setlevel value SL1 and the difference between these signals is given the right polarity for a negative feedback thereof to the resonance amplifiers RA1-RAn. Such DC signal generating means is on itself known, e.g. from Philips' Application Note of one chip AM radio IC TEA 5551T, dated October 1990.

Said first DC loop signal is supplied to a first input I1 of the AGC signal generating means CG. The AGC signal generating means CG derives from said first DC loop signal, first and second control signals Iq and Id, respectively. For the sake of clarity the control in gain and selectivity of the cascade of resonance amplifier RA1-Ran in the RF input circuit RFC function obtained with said first and second control signals Iq and Id is described hereinafter with respect to a single resonance amplifier, however is to be understood to apply to each resonance amplifier in the cascade.

The first and second control signals Iq and Id are being supplied through first and second outputs O1 and O2 of the AGC signal generating means CG to a common gain control input of said third and fourth transconductance amplifiers (TC3, TC4) and a common gain control input of said fifth and

sixth transconductance amplifiers (TC5, TC6), respectively. According to one of the aspects of the invention, the first and second control signals (Iq, Id) both increase at an increase of the first DC signal (A) and vice versa, the first control signal (Iq) significantly stronger than the second one (Id). This results in the overall receiver gain variation being shared between the fifth and sixth transconductance amplifiers (TC5, TC6) on the one hand and the third and fourth transconductance amplifiers (TC3, TC4) on the other hand within each of the cascade of resonance amplifier RA1-Ran in the RF input circuit RFC, while maintaining acceptable dynamic selectivity. Compared with the conventional receiver of US patent number 5,220,686 the negative resistance values provided by the third and fourth transconductance amplifiers (TC3, TC4) are smaller and therewith also their noise contribution in the partial compensation of the positive resistance value of the first and second parallel RC filters R1C1, R2C2.

The first AGC loop is effective for variations in the RF carrier level of the wanted RF signal. However, RF signals having a relatively large field strength with respect to the field strength of the wanted RF signal and occurring at relatively small frequency distances from the wanted RF signal, also being referred to as strong adjacent channels, cause the wideband output signal level of the RF input circuit RFC to exceed the dynamic input range of the synchronous demodulator SD in particular when occurring at close frequency distance from the wanted RF signal. In this unwanted mode of operation, also being referred to as overexcitation, the detection of the wanted RF signal in the synchronous demodulator SD is being severely deteriorated. According to a further aspect of the invention, the dynamic range of the wideband output signal level of the RF input circuit RFC, i.e. wideband input signal level of the

synchronous demodulator SD, is therefore being reduced to a value within the dynamic input range of the synchronous demodulator SD. For this purpose, a second AGC loop is applied, in which the output of the RF input circuit RFC is coupled through successively wideband level detecting means WD, second DC signal generating means DC2 and said AGC signal generating means CG to gain control inputs of the resonance amplifiers RA1-RAn of the RF input circuit RFC, as will be described in more detail hereinafter.

In said wideband level detecting means WD, the wideband RF output signal of the RF input circuit RFC is being detected to provide a wideband RF signal level indicative DC signal. This wideband RF signal level indicative DC signal is selected and further processed into a second DC loop signal DC2 in second DC signal generating means DC2. In this further processing, the wideband RF signal level indicative DC signal is being compared with a second setlevel value SL2, the difference between these signals is given the right polarity for a negative feedback thereof to the resonance amplifiers RA1-RAn, such that any deviation of said wideband RF signal level indicative DC signal in excess of said second setlevel value SL2 is suppressed. By a proper choice of the second setlevel SL2, the second AGC loop prevents the RF output signal of the RF input circuit RFC from exceeding the dynamic input range of the synchronous demodulator SD and therewith from overexcitation thereof. Unlike the first AGC loop, the second AGC loop is active only for values of the wideband RF signal level indicative DC signal exceeding said second setlevel SL2 and is inactive for smaller values thereof.

Said wideband level detecting means WD may include a wideband envelope detector or preferably a square law envelope detector as will be described in more detail with respect to Figure 3b. Said second DC signal is being

supplied to a second input I2 of said AGC signal generating means CG. In a practical embodiment, which takes into account the statistic distribution of normally occurring field strength values of transmitter signals over the RF frequency range of existing radio broadcast systems and which is optimized in minimum noise figure and maximum dynamic selectivity, the first and second control signals Iq and Id are being defined as:

$$I_q(A, BW) = I_q^* + A \quad \text{and}$$

$$I_d(A, BW) = I_d^* + 0,25A - BW,$$

in which  $I_q^*$  and  $I_d^*$  are scaling factors, and in which A and BW represent said first and second DC signals respectively. The proportionality factor of 0,25 is experimentally defined on the basis of the abovementioned statistic distribution of normally occurring field strength values of transmitter signals over the RF broadcast frequency range.

The derivation of Iq and Id from A and BW in the AGC signal generating means CG can be implemented with rather simple circuitry. The AGC process executed by the first and second AGC loops and obtaining stabilization of the RF carrier level indicative DC signal at said first setlevel value SL1 and the wideband RF signal level indicative DC signal will be explained in more detail with reference to Figure 4.

Figure 3a shows an alternative embodiment of the AGC signal generating means CG allowing for a stable AGC operation on both input and output signals of the synchronous demodulator being optimized in terms of minimum noise figure and maximum dynamic range. Herein, the first and second control signals are preferably defined by:

$$I_q(A, BW) = I_q^{**}(A - BW/BW^*)$$

$$I_d(A, BW) = A \cdot I_d^{**}(BW/BW^*)$$

in which  $I_q^{**}$ ,  $I_d^{**}$  and  $BW^*$  are scaling factors.

These formulas effectuate a dependency of the first and second control signals from the first and second DC signals,

which is inverse to the typical dependency of the overall gain and bandwidth of a resonance amplifier from the first and second control signals. This results in full separation or orthogonal control of the AGC operation on the gain of the resonance amplifier on the one hand by the first DC signal (A) and the selectivity or bandwidth thereof by the second DC signal (BW) on the other hand.

The implementation of the first and second DC signal generating means DC1 and DC2 belongs to the normal ability of the skilled man. Reference is made in this respect to Philips' Application Note of one chip AM radio IC TEA 5551T, dated October 1990.

To further secure stable AGC operation the second set level value is chosen to be greater than the first setlevel value. Practical values for the first and second setlevel values are 30mV and 3 mV, respectively.

Figure 3b is a block diagram of a square law envelope detector for use as wideband level detecting means WD in a receiver according to the invention. Such square law envelope detector is on itself known, e.g. from US patent number 4,905,307. For an application thereof in the receiver of Figure 2, the last resonance amplifier RAn in the cascade of the RF input circuit RFC is to be operated in the above phase quadrature mode, in which the RF output signal of the RF input circuit RFC is available as a pair of phase quadrature RF signals at quadrature voltage output terminals Vout and V'out. of the resonance amplifier RSn. The square law envelope detector is a type RMS detector in that it derives said wideband RF signal level indicative DC signal from said pair of phase quadrature RF output signals by quadrating the phase quadrature RF I and Q signal components thereof in first and second quadrating devices SQ1 and SQ2 and subsequent summation of these quadrated RF I and Q signal components in summation device SUM.

As in any other type RMS detector, the RF signal quadrating results in an increase of level differences between a weak wanted RF signal and its strong adjacent RF signals compared with non-RMS type envelope detectors, therewith improving the separation in the derivation of the first and second DC signals. In addition thereto the square law envelope detector does not require the filtering of higher order harmonics as needed in other types of RMS detectors.

Figure 4 shows in curves a-d various gain/bandwidth characteristics of a single resonance amplifier as applied in the RF input circuit RFC at various settings of the first and second control signals  $I_q$  and  $I_d$ . Suppose the RF carrier level indicative DC signal of an RF reception signal decreases below the first setlevel value  $SL_1$  at which gain/bandwidth characteristic of the resonance amplifier is represented by curve a, then in the first AGC loop, the first control signal  $I_q$  will increase, causing the resonance amplifier to increase in gain and selectivity (i.e. decrease in bandwidth) as represented by curve b, to allow for a stabilization of the RF carrier level indicative DC signal at said first setlevel value  $SL_1$ . Dependent on the RF field strength of strong adjacent channels relative to the field strength of the wanted RF signal and their frequency distance to the wanted RF signal, this selective gain increase may cause the wideband RF signal level indicative DC signal in the second AGC loop to exceed the second setlevel value  $SL_2$ . If so, then the second control signal  $I_d$  decreases, causing the gain of the resonance amplifier to decrease as well. This decrease in gain is frequency indifferent and results in a gain/bandwidth characteristics of the resonance amplifier amplifier e.g. as given in curve c. This decrease in gain causes the RF carrier level indicative DC signal to decrease below the first setlevel

value SL1 again, causing the first control signal Iq in the first AGC loop and the gain and selectivity of the resonance amplifier to increase further, as represented by curve d. This, however, may again cause the wideband RF signal level  
5 indicative DC signal in the second AGC loop to exceed the second setlevel value SL2, and so on and so forth until both RF carrier level indicative DC signal and wideband RF signal level indicative DC signal are stabilized at the first and second setlevel values SL1 and SL2, respectively. Note that  
10 the bandwidth of curve d is smaller than the bandwidth of curve c, whereas bandwidth of curve c is similar to the bandwidth of curve b, but in its turn smaller than the bandwidth of curve a. The final gain and selectivity setting of the resonance amplifier obtained with this iterative AGC  
15 process provide minimum noise figure and maximum dynamic selectivity.

While the invention has been particularly shown and described with reference to the preferred embodiments shown in the Figures, it will be understood by those skilled in  
20 the art that various changes in form and details may be made without departing from the spirit and scope of the invention.

For instance, the RF input circuit may comprise any number of single resonance amplifiers in the cascade and may  
25 suffice in principle with a single resonance amplifier, other weighting and scaling factors may be used in determining the dependency of the first and second control signals from the first and second DC signals. Also other types of demodulators and/or detection may be used to obtain  
30 DC signals indicative for the RF input and/or output signal levels of the signal demodulation means.

## Claims

1. Receiver comprising a resonance amplifier for selectively amplifying a modulated carrier signal being  
5 coupled to signal demodulation means for narrow band demodulation of said carrier signal providing an RF carrier level indicative, first DC signal (A) being supplied to a first input of AGC signal generating means, said resonance amplifier having a cascade of  
10 first and second transconductance amplifiers (TC1, TC2) being included in a loop, outputs thereof being coupled via first and second parallel RC filters (R1C1; R2C2) to inputs of the second and first transconductance amplifiers TC1, TC2), respectively, said loop also  
15 including means for signal inversion (INV), inputs and outputs of third and fourth transconductance amplifiers (TC3, TC4) being coupled to outputs of said first and second transconductance amplifiers (TC1, TC2), respectively, to effectuate a negative resistance value  
20 across said first and second parallel RC filters (R1C1, R2C2), respectively, varying with the gain of said third and fourth transconductance amplifiers (TC3, TC4), fifth and sixth transconductance amplifiers (TC5, TC6) being coupled between inputs and outputs of said resonance  
25 amplifier, characterized by said AGC signal generating means deriving first and second control signals (Iq, Id) from said first DC signal (A), said first control signal (Iq) being supplied to gain control inputs of said third and fourth transconductance amplifiers (TC3, TC4) and  
30 said second control signal (Id) being supplied to gain control inputs of said fifth and sixth transconductance amplifiers (TC5, TC6), the first and second control signals (Iq, Id) increasing at an increase of the first

DC signal (A) and vice versa, the first control signal (Iq) stronger than the second control signal (Id).

2. Receiver according to claim 1, characterized by wideband level detecting means following the resonance amplifier supplying a wideband RF signal level indicative, second DC signal (BW) to a second input of said AGC signal generating means, said second control signal (Id) varying with a variation of the second DC signal (BW).

3. Receiver according to claim 2, characterized in that said second control signal (Id) varies opposite to the second DC signal (BW).

4. Receiver according to claim 3, characterized in that said first control signal (Iq) varies substantially in correspondence with the first DC signal (A) and the second control signal (Id) in proportion with the first DC signal (A) and opposite to the second DC signal (BW).

5. Receiver according to claim 4, characterized in that the proportion by which the second control signal (Id) varies with the first DC signal (A) is in the order of magnitude of one quarter.

6. Receiver according to claim 2, characterized in that said second control signal (Id) decreases at a decrease of the second DC signal (BW).

7. Receiver according to claim 6, characterized by said first control signal (Iq) varying substantially in correspondence with the first DC signal (A) and opposite to the second DC signal (BW) and said second control signal (Id) varying substantially in correspondence with

the product value of the first and second DC signals (A and BW).

8. Receiver according to one of claims 2 to 7,  
5 characterized by said signal demodulation means and said wideband level detecting means being coupled through first and second DC signal generating means to the first and second inputs of said AGC signal generating means in which the RF carrier level and the wideband RF signal  
10 level are being compared with first and second setlevel values, respectively.
9. Receiver according to claim 8, characterized by the  
15 second set level value being greater than the first setlevel value.
10. Receiver according to one of claims 1 to 9,  
characterized by a local tuning oscillator being controlled by a tuning voltage and providing a local RF  
20 oscillator signal to a synchronous RF demodulator included in said signal demodulation means, said tuning voltage being supplied to gain control inputs of said first and second transconductance amplifiers of said resonance amplifier.
- 25 11. Receiver according to one of claims 2 to 10,  
characterized by said tuneable resonance amplifier supplying a pair of phase quadrature RF signals to a square law envelope detector included in said wideband  
30 level detecting means.

# INTERNATIONAL SEARCH REPORT

International Application No

PCT/EP 02/00528

A. CLASSIFICATION OF SUBJECT MATTER  
IPC 7 H03G3/30 H03J3/08

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 H03G H03J

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, PAJ

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	US 5 220 686 A (KASPERKOVITZ WOLFDIETRICH G ET AL) 15 June 1993 (1993-06-15) cited in the application the whole document ----	1
A	US 5 321 852 A (SEONG CHANG-YEOL) 14 June 1994 (1994-06-14) column 2, line 52 -column 3, line 64; figure 2 ----	1
A	US 6 057 735 A (CLOUTIER MARK) 2 May 2000 (2000-05-02) abstract -----	1

☐ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents :

\*A\* document defining the general state of the art which is not considered to be of particular relevance

\*E\* earlier document but published on or after the international filing date

\*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

\*O\* document referring to an oral disclosure, use, exhibition or other means

\*P\* document published prior to the international filing date but later than the priority date claimed

\*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

\*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

\*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

\*G\* document member of the same patent family

Date of the actual completion of the international search

26 March 2003

Date of mailing of the international search report

02/04/2003
